# Statistical Approaches to Evaluate Analytical Similarity Guidance for Industry

This draft guidance, when finalized, will represent the current thinking of the Food and Drug Administration (FDA or Agency) on this topic. It does not establish any rights for any person and is not binding on FDA or the public. You can use an alternative approach if it satisfies the requirements of the applicable statutes and regulations. To discuss an alternative approach, contact the FDA staff responsible for this guidance as listed on the title page.

## I. INTRODUCTION

This guidance is intended to provide advice on the evaluation of analytical similarity to sponsors interested in developing biosimilar products for licensure under section 351(k) of the Public Health Service Act (PHS Act) (42 U.S.C. 262(k)). This evaluation is to support the demonstration that a proposed biosimilar product (hereinafter *proposed biosimilar* or *biosimilar*) is highly similar to a reference product licensed under section 351(a) of the PHS Act. Specifically, this guidance describes the type of information a sponsor of a proposed biosimilar product should obtain about the structural/physicochemical and functional attributes of the reference product, how that information is used in the development of an analytical similarity assessment plan for the proposed biosimilar, and the statistical approaches recommended for evaluating analytical similarity.

This guidance is one in a series of guidance documents that FDA is developing or has developed to implement the Biologics Price Competition and Innovation Act of 2009 (BPCI Act). It serves as a companion document to the guidance for industry *Quality Considerations in Demonstrating Biosimilarity of a Therapeutic Protein Product to a Reference Product*.<sup>1</sup>

In general, FDA's guidance documents do not establish legally enforceable responsibilities. Instead, guidance documents describe the Agency's current thinking on a topic and should be viewed only as recommendations, unless specific regulatory or statutory requirements are cited. The use of the word *should* in FDA guidance documents means that something is suggested or recommended, but not required.

## II. BACKGROUND AND SCOPE

The BPCI Act created an abbreviated licensure pathway under section 351(k) of the PHS Act (42 U.S.C. 262(k)) for biological products shown to be biosimilar to or interchangeable with an U.S.-

<sup>1</sup> We update guidances periodically. To make sure you have the most recent version of a guidance, check the FDA Drugs guidance web page at <https://www.fda.gov/Drugs/GuidanceComplianceRegulatoryInformation/Guidances/default.htm>, or the CBER guidance web page at <https://www.fda.gov/BiologicsBloodVaccines/GuidanceComplianceRegulatoryInformation/Guidances/default.htm>.

*Contains Nonbinding Recommendations*

*Draft — Not for Implementation*

40 licensed biological reference product (see sections 7001 through 7003 of Public Law 111-148).  
41 Section 351(i) of the PHS Act defines *biosimilarity* to mean “that the biological product is highly  
42 similar to the reference product notwithstanding minor differences in clinically inactive components”  
43 and that “there are no clinically meaningful differences between the biological product and the  
44 reference product in terms of the safety, purity and potency of the product.”<sup>2</sup> A 351(k) application for  
45 a proposed biosimilar product must include information demonstrating biosimilarity based on data  
46 derived from, among other things, “analytical studies that demonstrate that the biological product is  
47 highly similar to the reference product notwithstanding minor differences in clinically inactive  
48 components.”<sup>3</sup>

49  
50 Since the passage of the BPCI Act in 2009, FDA has released a number of guidance documents on  
51 demonstrating biosimilarity, including the guidances for industry *Scientific Considerations in*  
52 *Demonstrating Biosimilarity to a Reference Product* (final issued in 2015) and *Quality Considerations*  
53 *in Demonstrating Biosimilarity of a Therapeutic Protein Product to a Reference Product* (final issued  
54 in 2015). Based on the statutory definition of *biosimilarity*, these guidance documents are intended (1)  
55 to assist sponsors in demonstrating biosimilarity for submitting a marketing application under section  
56 351(k) of the PHS Act and (2) to describe FDA’s current thinking on scientific principles to be  
57 considered in determining biosimilarity. Specifically, in the *Scientific Considerations in*  
58 *Demonstrating Biosimilarity to a Reference Product* guidance for industry, FDA described the totality-  
59 of-the-evidence approach that FDA would use in the review of biosimilar applications. The results of  
60 statistical analyses conducted to support a demonstration that a proposed product is “highly similar”  
61 to U.S.-licensed reference product (hereinafter the *reference product* or the *U.S.-licensed reference*  
62 *product*) are considered within the context of totality-of-the-evidence in determining if a proposed  
63 product is biosimilar to a reference product. The *Quality Considerations in Demonstrating*  
64 *Biosimilarity of a Therapeutic Protein Product to a Reference Product* guidance for industry describes  
65 the Agency’s recommendations to sponsors on the scientific and technical information (including  
66 analytical studies to support a demonstration that a proposed biosimilar is highly similar to the  
67 reference product), for the chemistry, manufacturing, and controls (CMC) section of a marketing  
68 application for a proposed product submitted under section 351(k) of the PHS Act.

69  
70 The objective of this guidance is to assist sponsors in demonstrating, through an evaluation of the  
71 analytical similarity of the proposed biosimilar and reference product, that the proposed biosimilar and  
72 reference product are highly similar to support licensure under section 351(k) of the PHS Act. In  
73 general, an analytical similarity assessment involves a comparison of structural/physicochemical and  
74 functional attributes using multiple lots of the proposed biosimilar product and the reference product.

75  
76 Conducting appropriate statistical analyses in the evaluation of analytical similarity can provide a high  
77 degree of confidence in the results and reduce the potential for bias. However, there are many  
78 challenges in designing the statistical analyses to be performed. First, there may be a limited number  
79 of reference product lots, and those obtained may be the result of biased sampling, leading to  
80 imprecise and possibly inaccurate estimates of the distributions of important quality attributes for the

*Draft — Not for Implementation*

81 reference product. Second, there may also be a limited number of proposed biosimilar lots, and the  
82 available lots may not reflect the true variability of biosimilar product manufacturing. Third, there are  
83 a large number of potential quality attributes that can be compared in an evaluation of analytical  
84 similarity, and subjecting all of these attributes to formal statistical tests in the context of limited lots  
85 could lead to concluding incorrectly that a large number of truly highly similar products are not highly  
86 similar.

87  
88 To address these challenges, the Agency recommends using a risk-based approach in the analytical  
89 similarity assessment of quality attributes. This approach to the evaluation of analytical similarity  
90 consists of several steps. The first step is a determination of the quality attributes that characterize the  
91 reference product in terms of its structural/physicochemical and functional properties. In the second  
92 step, these quality attributes are then ranked according to their risk of potential clinical impact. Third,  
93 these attributes/assays are evaluated according to one of three tiers of statistical approaches based on a  
94 consideration of risk ranking as well as other factors. It should be noted, however, that some attributes  
95 may be important but not amenable to quantitative evaluation.

96  
97 This guidance is not intended to describe the Agency's expectations for determining the adequacy of  
98 similarity for initiating clinical studies in a biosimilar development program, nor is it intended to  
99 describe the expectations for developing the manufacturing control strategy.

100  
101 The document is structured as follows: Section III describes the quantity and quality of both reference  
102 product and biosimilar lots that we generally believe are scientifically necessary for evaluating  
103 analytical similarity; Section IV describes general principles for the evaluation of analytical similarity,  
104 including the use of a risk assessment to rank attributes and a tiered approach to the evaluation of  
105 analytical similarity.

106  
107 **III. REFERENCE AND BIOSIMILAR PRODUCTS**

108  
109 The Agency recommends that the analytical similarity evaluation begin with an understanding of the  
110 structural/physicochemical and functional attributes of the reference product. Based on information  
111 obtained about these attributes during development of the proposed biosimilar, the sponsor should  
112 develop an analytical similarity assessment plan (see section IV.A). A key component of this plan is  
113 the description of lots available for similarity testing. The following factors should be considered  
114 when selecting lots to be used in the analytical similarity assessment:

- 115
- 116 • Number of Reference Product Lots - To establish meaningful similarity acceptance criteria,  
117 sponsors should acquire a sufficient number of reference product lots. We recommend a  
118 minimum of 10 reference product lots be sampled. In cases where limited numbers of  
119 reference product lots are available (e.g., for certain orphan drugs), alternate analytical  
120 similarity assessments should be proposed and discussed with the Agency.
  - 121
  - 122 • Number of Biosimilar Product Lots - To allow for meaningful comparisons, we  
123 recommend a minimum of 10 biosimilar lots be included in the analytical similarity  
124 assessment.

- Variability in Reference Product Lots - The reference product lots selected should represent the variability of the reference product. Lots with remaining expiry spanning the reference product shelf life should be selected. The date of the analytical testing as well as the product expiration date should be provided in the application. Expired reference product should not be included in the similarity assessment to avoid bias.
  - Accounting for Reference Product and Biosimilar Product Lots - Sponsors should account for all of the reference product lots available to them. A list should be provided in the application of all lots that were evaluated in any manner even if a particular lot was not used in the final similarity assessment. The list should include the disposition of each lot and the specific physicochemical, functional, animal, and clinical studies for which a lot was used. When a lot is specifically selected to be included in or excluded from certain studies, a justification should be provided. Similar information on every manufactured drug substance and drug product lot of the proposed biosimilar product should also be provided.
  - U.S.-Licensed Reference Product and Other Comparators - The analytical similarity acceptance criteria should be derived using data from an analysis of the U.S.-licensed reference product, and the similarity assessment should be based on a direct comparison of the proposed biosimilar product to the U.S.-licensed reference product. As a scientific matter, combining data from the U.S.-licensed reference product and comparator products approved outside of the United States to determine the acceptance criteria or to perform the analytical similarity assessment generally would not be expected to support a determination that the proposed biosimilar is highly similar to the U.S.-licensed reference product. For example, combining data from U.S.-licensed reference product and non-U.S.-licensed comparator products may result in broader similarity acceptance criteria than would be obtained by relying solely on U.S.-licensed reference product lots due to increased variability of the products. Sponsors are encouraged to discuss with FDA, during drug development, any plans to use data derived from products approved outside of the United States.<sup>4</sup>
  - Biosimilar Lots Manufactured with Different Processes - It may be possible to combine data in the analytical similarity assessment from proposed biosimilar product lots manufactured with different processes and/or at different scales. However, data should be provided in the 351(k) biologics license application to support comparability of any materials manufactured with the different processes and/or scales.

---

<sup>4</sup> See the guidance for industry *Biosimilars: Questions and Answers Regarding Implementation of the Biologics Price Competition and Innovation Act of 2009*.

166 **IV. GENERAL PRINCIPLES FOR EVALUATING ANALYTICAL SIMILARITY**

167  
168 Analytical similarity should be assessed by using appropriate statistical methods to evaluate the  
169 analytical data. Methods of varying statistical rigor should be applied depending on the risk ranking of  
170 the quality attributes. Sponsors should develop an analytical similarity assessment plan that includes  
171 their proposed statistical approach to evaluation and then should discuss this approach with the  
172 Agency as early in the development program as feasible. The final analytical similarity report, which  
173 should include the analytical similarity assessment plan, should be included when a 351(k) biologics  
174 license application is submitted. The development of the analytical similarity assessment plan is the  
175 topic of the first subsection below, followed by a discussion of FDA’s current thinking on the  
176 statistical methods to be applied for evaluation.  
177

178 **A. Analytical Similarity Assessment Plan**

179  
180 We recommend that the analytical similarity assessment plan be carefully designed to identify and  
181 address all factors that could impact the determination about whether the proposed biosimilar is highly  
182 similar to the reference product. Some factors that may need to be considered include:  
183

- 184 • Differences in age of the lots produced at testing: It is recognized that differences in the age of  
185 the proposed biosimilar and reference product lots at the time of testing may result in analytical  
186 differences. There should, therefore, be a pre-specified plan to address how changes in  
187 attributes over the shelf-life will be incorporated into the determination of the similarity  
188 acceptance criteria.  
189
- 190 • Multiple testing results: When there are multiple testing results for the same lot with a given  
191 quality attribute or assay, the biosimilar applicant should pre-specify which results will be  
192 selected for analytical similarity assessment.  
193
- 194 • Assay performance: The assay methodologies and assay designs used in the analytical  
195 similarity assessment should be carefully considered and optimized, as needed. Poor assay  
196 performance, including high assay variability, should not be used to justify selection of either a  
197 particular evaluation tier or an inappropriately broad similarity acceptance criteria.  
198
- 199 • Differences in attributes that will be considered acceptable: It may be known in advance that a  
200 difference less than or equal to a certain amount for a particular quality attribute would not be  
201 expected to have a clinical impact. In this situation, supporting information and an adequate  
202 justification for the allowable differences should be provided in the application.  
203

204 We recommend that the analytical similarity assessment plan be developed in four stages,  
205 corresponding to the following activities:  
206

- 207 • Development of the risk ranking of the reference product’s quality attributes based on the  
208 potential impact on the clinical performance categories (i.e., the product’s activity as well as  
209 pharmacokinetic/pharmacodynamic (PK/PD), safety, and immunogenicity profiles)  
210

## *Contains Nonbinding Recommendations*

*Draft — Not for Implementation*

- 211 • Determination of the statistical methods to be used for evaluating each quality attribute based  
212 on the risk ranking and on other factors  
213
- 214 • Development of the statistical analysis plan  
215
- 216 • Finalization of the analytical similarity assessment plan  
217

218 These four stages are described in more detail in the following subsections.  
219

### 220 *I. Development of Risk Ranking of Attributes* 221

222 FDA recommends that biosimilar sponsors develop a risk assessment tool to evaluate and rank the  
223 reference product quality attributes in terms of potential clinical impact.<sup>5</sup> The risk assessment tool  
224 should be developed considering, at a minimum, the following two factors:  
225

- 226 • Potential impact of an attribute on clinical performance: Specifically, we recommend that  
227 sponsors consider the impact of an attribute on activity as well as on  
228 pharmacokinetic/pharmacodynamic (PK/PD), safety, and immunogenicity profiles. For  
229 example, sponsors should consider available public information, as well as the sponsor's  
230 characterization of the reference product, in determining the potential impact of an attribute on  
231 clinical performance.  
232
- 233 • The degree of uncertainty around a certain quality attribute: For example, when there is  
234 limited understanding of the clinical impact of an attribute, we recommend that that attribute be  
235 ranked as having higher risk because of the uncertainty involved.  
236

237 FDA recommends that an attribute that is a high risk for any one of the performance categories (i.e.,  
238 activity, PK/PD, safety, or immunogenicity) should be classified as high risk. Ideally, the risk  
239 assessment tool should result in a list of attributes ordered by the risk to the patient. The risk scores  
240 for attributes should, therefore, be proportional to patient risk. Because there may be a limited number  
241 of attributes that can be evaluated with equivalence testing (see section IV.A.2), attributes that are  
242 known to be of high risk to patients (i.e., high impact attributes) should be a priority over attributes  
243 with unknown but potentially high risk (i.e., attributes with a high-risk ranking due to uncertainty).  
244 The scoring criteria used in the risk assessment should be clearly defined and justified in the analytical  
245 similarity assessment plan, and the risk ranking for each attribute should be justified with appropriate  
246 citations to the literature and data provided.  
247  
248  
249

---

<sup>5</sup> Certain quality evaluations of the reference product—e.g., its degradation rates, which are determined from stability or forced degradation studies—generally would not be included in the risk ranking. However, these evaluations will still factor into the assessment of the analytical similarity of the proposed biosimilar and reference product.

*Contains Nonbinding Recommendations*

*Draft — Not for Implementation*

2. *Determination of the Statistical Methods to be Used*

FDA's current approach to evaluating analytical similarity is to define three tiers corresponding to the use of three different methods for comparing attributes. FDA believes that the use of these three tiers with appropriate similarity acceptance criteria should help support a demonstration that the proposed biosimilar is highly similar to the reference product. Equivalence testing (Tier 1) is typically recommended for quality attributes with the highest risk ranking and should generally include assay(s) that evaluate clinically relevant mechanism(s) of action of the product for each indication for which approval is sought. The use of quality ranges (Tier 2) is recommended for quality attributes with a lower risk ranking, and an approach that uses visual comparisons (Tier 3) is recommended for quality attributes with the lowest risk ranking. The three methods are described in Section IV.B.

In addition to risk ranking, however, other factors should be considered in determining which tier of statistical evaluation should be applied to a particular attribute or assay. Although many attributes may be considered high risk, subjecting all of these attributes to Tier 1 testing may result in a false negative conclusion (i.e., a determination that a product is not highly similar when it truly is). Some additional factors, besides risk, that should be considered when determining the appropriate tier include:

- Level of the attribute: An attribute of the reference product known to be of high risk but present at a level that is unlikely to have significant clinical impact could potentially be assessed at a lower tier. To justify placing a high risk attribute in a lower tier for this reason, the level of the attribute should be confirmed in both the reference product (as determined by the proposed biosimilar sponsor's analysis of the reference product) and the proposed biosimilar product. The selected limits regarding the level of an attribute should be defined and justified. The justification should also include consideration of how the level of the attribute changes over time.
- Assays used for assessing the attribute: Although multiple, orthogonal assays are encouraged for assessing a single attribute, not all assays need to be included in the same tier of assessment. The assay with the best performance characteristics for detecting product differences should be used for testing with the highest tier methods, while other assays should be used for testing with lower tier methods. A justification should be provided for the assays selected for testing at each tier.
- Types of attributes/assays: Some attributes or the assays used to assess the attribute will, by their nature, be excluded from certain statistical evaluations. For example, compendial assays, qualitative assays, or limit assays might be excluded from evaluation with Tier 1 and, in some cases, Tier 2 methods. The analytical similarity assessment plan should clearly define the conditions used to exclude assays from evaluation at any tier.

Applicable data and cited literature should be provided in the application to support the use of any additional factors in determining the appropriate tier of statistical assessment.

296 3. *Development of the Statistical Analysis Plan*

297  
298 A detailed statistical analysis plan should be developed and included in the analytical similarity  
299 assessment plan because the statistical aspects of the evaluation will impact whether or not the  
300 similarity acceptance criteria are ultimately met. The plan for the statistical evaluation of analytical  
301 similarity requires the selection of design features from among many possibilities. These design  
302 features include the following five factors:

- 303 • the choice and risk ranking of attributes;  
304 • the statistical approach (tier) for assessing each attribute;  
305 • the number of proposed biosimilar and reference product lots to be evaluated for each attribute,  
306 and the number of replicates to be evaluated per lot;  
307 • for each attribute, a determination of the largest acceptable difference between the proposed  
308 biosimilar and reference product that is considered to not have clinical impact;  
309 • the methods of statistical analysis for each tier, and the type of assay(s) used to evaluate each  
310 attribute.

311  
312 It is well known that bias may be introduced when there is an opportunity to select the most desirable  
313 result from a number of results obtained; consequently, the probability of a false positive result may be  
314 increased, and any estimated differences between the products are likely to be biased toward  
315 equivalence. Therefore, to minimize bias and the chance of erroneous conclusions, the statistical  
316 analysis plan should be pre-specified to the fullest extent possible. In some cases, it may be necessary  
317 to first collect preliminary data (e.g., to get an initial estimate of the variability of the reference  
318 product's attribute or to select an assay at the outset before finalizing the statistical analysis plan).

319  
320 4. *Finalization of the Analytical Similarity Assessment Plan*

321  
322 The final analytical similarity assessment plan should include the risk ranking of attributes, the  
323 specification of tiers of evaluation to be used for each attribute/assay, and the final statistical analysis  
324 plan. The plan should specify the anticipated availability of both proposed biosimilar and reference  
325 product lots for evaluation of each attribute/assay and should include a rationale as to why the  
326 proposed number of lots will be sufficient for evaluation purposes. The analytical similarity  
327 assessment plan should be discussed with the Agency as early in the biosimilar development program  
328 as possible so that agreement can be reached on which attributes/assays should be evaluated in each  
329 tier. The final analytical similarity assessment plan should be submitted to the Agency prior to  
330 initiating the final analytical assessments; typically this would be done in connection with a meeting  
331 with the Agency.

332  
333 **B. Statistical Methods for Evaluation**

334  
335 The Agency's current thinking on the statistical evaluation of analytical similarity is described in this  
336 section. Sponsors that intend to propose alternative statistical approaches to the Agency should do so  
337 during the analysis planning stage.  
338  
339

*Contains Nonbinding Recommendations*

*Draft — Not for Implementation*

340           1.       Tier 1 (Equivalence Test)

341

342                   a.       Hypotheses and statistical tests

343

344 Analytical similarity of the quality attributes determined to have the highest potential clinical impact  
345 (based on the risk ranking and other factors, as described in section IV.A) should be evaluated through  
346 formal statistical tests of equivalence. Equivalence of attributes measured on a continuous scale can  
347 be assessed by testing the difference in means between the proposed biosimilar and reference product.

348 In the following formulas,  $\mu_T$  and  $\mu_R$  denote the population means, and  $\sigma_T^2$  and  $\sigma_R^2$  denote the population  
349 variances of the proposed biosimilar and reference product, respectively. To test for equivalence in  
350 means, the null and alternative hypotheses are given by

351

$$H_0 : \mu_T - \mu_R \leq -\delta \text{ or } \mu_T - \mu_R \geq \delta$$

352

$$H_a : -\delta < \mu_T - \mu_R < \delta$$

353

354 In these formulas,  $\delta$  is a positive number denoting the largest acceptable difference between the  
355 proposed biosimilar and reference product that is considered to not have clinical impact (i.e., the  
356 “equivalence margin”). Analytical similarity is supported if the null hypothesis of non-equivalence,  
357  $H_0$ , is rejected. In other words, the statistical equivalence in means is established if the results of the  
358 statistical analysis indicate, with high confidence, that

359

$$-\delta < \mu_T - \mu_R < \delta$$

360

361 A test of the equivalence hypothesis can be conducted by requiring the simultaneous rejection of the  
362 following two one-sided null hypotheses:

363

$$H_{01} : \mu_T - \mu_R \leq -\delta \text{ vs. } H_{a1} : \mu_T - \mu_R > -\delta$$

364

$$H_{02} : \mu_T - \mu_R \geq \delta \text{ vs. } H_{a2} : \mu_T - \mu_R < \delta$$

365

366 The probability of making a Type I error (i.e., declaring incorrectly that a biosimilar product’s  
367 particular attribute is equivalent to a reference product’s particular attribute) for a test of the  
368 equivalence hypothesis is controlled at the prespecified level  $\alpha$ , provided each of the two one-sided  
369 hypotheses,  $H_{01}$  and  $H_{02}$ , is tested at the same level  $\alpha$ .<sup>6</sup>

370

371 A convenient way to simultaneously test the two null hypotheses defining equivalence is through a  
372 confidence-interval-based test. If the  $(1-2\alpha)100\%$  two-sided confidence interval of the mean  
373 difference lies within  $(-\delta, \delta)$ , then both null hypotheses are rejected and the Type I error probability is  
374 controlled at level  $\alpha$  for a conclusion of equivalence. For example, a 5% Type I error probability is  
375 obtained by requiring a 90% confidence interval to lie within  $(-\delta, \delta)$ .

b. Margin determination

Determining an appropriate margin is a critical but challenging step for equivalence testing in any setting. Ideally, it would be possible to establish and pre-specify a biologically or clinically meaningful equivalence margin based on scientific knowledge or past experience. Often, however, such a margin is not readily available for every quality attribute deemed important enough for Tier 1 testing in a biosimilar development program. With this limitation, FDA currently recommends use of an equivalence margin that is a function of the reference product's variability for the attribute being tested. Specifically, the equivalence margin should be in the form of  $f \times \sigma_R$ , where  $f$  is a fixed constant, and  $\sigma_R$  is the standard deviation of the quality attribute of the reference product. This suggested form of the equivalence margin is based on three criteria: (1) the goal of ensuring that values of the attribute being tested for the proposed biosimilar tend to fall within the reference product distribution, (2) the desire to have a unified representation of the margin for all Tier 1 quality attributes despite different levels of variability, and (3) the goal of having sufficient power for practical sample sizes.

After examining a range of possible values for the constant  $f$ , FDA determined that a reasonable value should be 1.5. With  $\delta = 1.5 \sigma_R$ , the test generally should support equivalence if the 90% confidence interval of the difference in means lies within the interval  $(-1.5 \sigma_R, 1.5 \sigma_R)$  (i.e., the lower limit of the 90% confidence interval for the difference in means is greater than  $-1.5 \sigma_R$  and the upper limit is less than  $1.5 \sigma_R$ ). Use of this multiplier in computing the equivalence margin results in a test with reasonable properties under what we feel are realistic conditions. For example, if 10 biosimilar and 10 reference product lots are available, and the variability of the attribute for the reference product ( $\sigma_R$ ) is known and not estimated from the sponsor's data, this test has adequate power (i.e., at least 85%) to reject the null hypotheses in favor of equivalence when the true underlying mean difference between the proposed biosimilar and the reference products is small, namely, equal to  $\sigma_R / 8$ , assuming a test of size  $\alpha = 0.05$ . If the true difference between products is less than  $\sigma_R / 8$ , power will be increased.

A limitation of the proposed approach to setting the equivalence margin is that  $\sigma_R$  is usually not known and must be estimated from the current reference product lots available to the sponsor. If one uses a t-test and does not consider the uncertainty in the estimate of the margin, the Type I error probability may be inflated. Alternative tests can be constructed to account for this additional uncertainty, but additional research is needed to better understand the operating characteristics of these tests (such as the small sample size performance of a Wald<sup>7</sup> test based on large-sample approximations).

2. Tier 2 (Quality Range Approach)

For Tier 2, the similarity acceptance criteria based on reference product results for a specific quality attribute should be defined as  $(\hat{\mu}_R - X \hat{\sigma}_R, \hat{\mu}_R + X \hat{\sigma}_R)$ , where  $\hat{\mu}_R$  is the sample mean and  $\hat{\sigma}_R$  is the sample standard deviation based on the reference product lots. The multiplier ( $X$ ) should be scientifically justified for that attribute and discussed with the Agency. Based on our experience to

## *Contains Nonbinding Recommendations*

*Draft — Not for Implementation*

416 date, methods such as the tolerance interval approach and the min-max approach are not  
417 recommended.<sup>8</sup>

418

419 Analytical similarity generally should be demonstrated for a quality attribute if a sufficient percentage  
420 of test lot values (e.g., 90%) fall within the quality range defined above for that attribute. The lots  
421 used for Tier 2 testing should, if possible, be the same as those used for Tier 1 testing.

422

### 423 3. *Tier 3 (Visual Displays)*

424

425 Attributes to be evaluated in Tier 3 should correspond either to those of lowest risk for potential  
426 clinical impact or those attributes which are important but not amenable to formal tests of hypotheses  
427 or quantitative evaluation. Various forms of visual displays may be used to compare the distribution  
428 of values from the proposed biosimilar and reference lots, and a subjective determination of the  
429 similarity should be made based on those displays. The lots used for the Tier 3 evaluation should be  
430 the same as, or a subset of, the lots used for Tier 1 and Tier 2 evaluations. The number of lots needed  
431 for the Tier 3 evaluation can depend upon a number of factors, including, for example, the expected  
432 lot-to-lot variability of the attribute. In cases where limited lot-to-lot variability is expected, a single  
433 lot of the proposed biosimilar and reference product for the Tier 3 evaluation may be acceptable.

434

### 435 4. *Additional Considerations*

436

437 We also recommend considering the following:

438

- 439 • The variance of an attribute (e.g.,  $\sigma_R^2$ ) encompasses both the within-lot and between-lot  
440 variance components. It is recommended that sponsors examine the contribution of the two  
441 variance components, as estimated from their lots, to help understand the performance of the  
442 assay. High assay variability generally is not an appropriate justification for a large value of  $\delta$ .  
443 Instead, the assay should be optimized and/or the number of replicates per lot should be  
444 increased to reduce variability. We note that, in either case, lots of both the proposed  
445 biosimilar and the reference product should be assessed with the same number of replicates for  
446 that attribute, and the margin and all subsequent calculations should be defined using all lot  
447 values.
- 448
- 449 • For all quantitative quality attributes, including those subject to Tier 1 and 2 evaluations,  
450 descriptive statistics and visual displays should be used to present the reference and proposed  
451 biosimilar product distributions. In addition, the sponsor should submit sufficient data in its  
452 application to allow the Agency to conduct independent analyses.
- 453
- 454 • When the calculated equivalence margins or quality ranges are too wide or narrow, the Agency  
455 may adjust them to more appropriate levels.
- 456

*Draft — Not for Implementation*

457 It is important to note that FDA's final assessment as to whether a proposed biosimilar is highly  
458 similar to the reference product is made upon the totality of the evidence, rather than the passing or  
459 failing of the analytical similarity criteria of any one tier or any one attribute. For example, the  
460 Agency generally will consider the impact of an enhanced manufacturing control strategy when  
461 making this final assessment.
